

ヤング係数測定方法

(The method for measuring
young's modulus)

■ 静的弾性係数

(Static method of measuring Young's modulus of elasticity)

→ destructive

■ 動的弾性係数

(Dynamic method of measuring Young's modulus of elasticity)

→ non-destructive

Static method

Young's modulus in bending

$$E = \frac{a(3L^2 - 4a^2)(F_2 - F_1)}{48I(w_2 - w_1)}$$

◆ a : 荷重-支点間距離 (mm) The distance between a support point and a load point

◆ L : 支点間距離 (mm) The distance between support points

◆ I : 断面二次モーメント (mm⁴) Cross-sectional secondary moment

◆ F₂ - F₁ : 最大荷重の4割値と1割値の差 (N)

0.4 × P_{max} - 0.1 × P_{max}

◆ w₂ - w₁ : F₂ - F₁ に対応するたわみ量 (mm)

The deflection correspond to “F₂-F₁”

dynamic method(E_{fr})

$$E_{fr} = 4 \times f^2 \times l^2 \times \rho$$

- ◆ f : 基本振動数 number of vibration (Hz)
- ◆ l : 棒の長さ length of timber (m)
- ◆ ρ : 棒の密度 density ($\text{kg} \cdot \text{m}^{-3}$)

Modulus of dynamic elasticity(E_{afb})

first order
vibration

$$E = (2\pi f l^2 / i m^2)^2 \rho$$

- ◇ f : 1次曲げ固有振動数 first order vibration about bending
- ◇ l : 長さ the length of the timber
- ◇ i : 断面2次半径 radius of gyration of area
- ◇ m : constant (4.730)

- Modulus of dynamic elasticity is higher than modulus of static elasticity by 5~10%.
- That difference comes from the effect of plastic deformation.
